User Comfort with Android Background Resource Accesses in Different Contexts

Blinded for Submission

ABSTRACT

Android apps ask users to allow or deny access to sensitive resources the first time the app needs them. Prior work has shown that users decide whether to grant these requests based on the context. In this work, we investigate user comfort level with resource accesses that happen in a background context, meaning they occur when there is no visual indication of a resource use. For example, accessing the device location after a related button click would be considered an interactive access, and accessing location whenever it changes would be considered a background access. We conducted a 2,198-participant fractional-factorial vignette study, showing each participant a resource-access scenario in one of two mock apps, varying what event triggers the access (when) and how the collected data is used (why). Our results show that both when and why a resource is accessed are important to users’ comfort. In particular, we identify multiple meaningfully different classes of accesses for each these factors, showing that not all background accesses are regarded equally. Based on these results, we make recommendations for how designers of mobile-privacy systems can take these nuanced distinctions into account.

1. INTRODUCTION

Android apps potentially have access to a range of sensitive resources, such as location, contacts, and SMS messages. As a result, Android and similar systems face a critical privacy and usability trade-off: when should the system ask the user to authorize an app to access sensitive resources? Requesting permissions too often can overburden the user; requesting permission too infrequently can lead to security violations.

There has been significant research into this question, much of which shows that users’ access-control decisions depend on the context, including when and why the access attempt is made [7, 27, 29, 37, 42, 44]. However, this prior work has typically focused on individual aspects of context in isolation, such as app behavior at the point of resource-access [29, 44, 45], or the reason the app requires access to the sensitive resource [27]. In particular, much of this work relies on a binary distinction between foreground and background accesses—sometimes defined as whether the app is visible on the screen [44, 45], and sometimes defined as whether the resource access is explicitly triggered by a specific user interaction [29, 35]. (Section 2 discusses related work in more detail.)

In this paper, we investigate more deeply how users understand resource uses that occur in the background, which we broadly define as not explicitly and obviously caused by a user interaction. We examine whether different kinds of background uses are viewed similarly, or whether more fine-grained distinctions are required for user comprehension.

In our investigation, we consider a broad range of possible background accesses, drawn in part from existing literature and in part from reverse-engineering the behavior of popular apps. We examine the context of these background accesses along two key axes: when and why the resource access is triggered. We consider four cases for when: after an Interaction (this is a non-background case, as a control), due to Prefetching, by a Change to a resource such as the device’s location changing, or after an unrelated UI action, which we refer to as a UI Background access. We also consider five cases for why: to Personalize the app, to get data from an app Server, to support Analytics to improve the app, to provide Ads, or for no given reason (NA). We consider these cases for a mock Dating app and a mock Ride Sharing app, and for three sensitive resources: Location, Contacts, and SMS messages.

We performed a 2,198-participant, between-subjects online vignette survey investigating users’ comfort across 52 conditions selected from the full-factorial set. Each participant viewed a slideshow of a mock app being used and then a diagram illustrating when and why the app accessed a selected sensitive resource. The participant was then asked whether they would be comfortable using an app that behaved similarly and whether they would recommend such an app to friends. (Section 3 describes our methodology, and Section 4 reports participant demographics.)

We found that both the why and when aspects of context played a significant role in users’ expressed comfort with background accesses. Background accesses that shared data with third parties for advertising and analytics were more objectionable than accesses providing personalized features, even when data was sent off device to the app developer. Perhaps unsurprisingly, of the third-party accesses, those
associated with with advertising were the least acceptable. Additionally, if no reason for access is provided, participants were likely to assume that the data is accessed for personalization. However, perhaps due to uncertainty about whether this assumption is valid, participants were less comfortable in this case than when personalization was explicitly specified.

While all background accesses were viewed as less acceptable than interactive accesses, participants did not react to all background accesses equally. Participants were significantly more comfortable with background accesses when the app is on-screen than when it is off-screen, even when the resource access is not clearly tied to the app’s UI. (Section 5 discusses our results.)

Based on these results, we make several design recommendations: that apps explicitly differentiate uses in different contexts, that systems provide better incentives to explain benign uses to users (e.g., when the data is used only for personalities), and that privacy policies track not just when data is used, but also where it flows (to explain why). (Section 6 presents our design recommendations.)

2. RELATED WORK

In early versions on Android, users were asked to authorize permissions whenever a new app was installed. Multiple studies showed that users did not understand the privacy risks associated with permissions under this model. Felt et al. found that only 17% of their study participants paid attention to the permissions they granted and just 3% fully understood what those permissions could be used to access [15]. Kelley et al. showed that users found the terms and wording of Android permissions hard to understand [22]. Additionally, other researchers demonstrated that users were unable to make informed decisions on whether to install an app because they did not know the context of the resource use, instead relying on their expectations of the app’s behavior [3, 25, 37, 42].

Android M [16] and later versions prompt users to grant or deny access to a permission the first time it is required by the app. This model is commonly referred to as Ask-On-First-Use (AOFU). Andrriotis et al. found that users feel they have more control of their privacy with AOFU [1, 2]. Bonne et al. showed that users commonly deny a permission and subsequently run the app to determine whether it is truly required [7].

Unfortunately, further work has shown that even under AOFU, users are still not provided with enough context to make informed decisions [7, 29, 37, 42]. In some cases, AOFU may lead the user to make incorrect decisions due to broken assumptions [29]. On the other hand, users experience warning fatigue when presented with too many permission dialogs [6]. Multiple researchers have shown that including a permission’s purpose (e.g., feature personalization, advertising) has a significant effect on user comfort [4].

Our study focuses on background resource accesses, by which we mean accesses with no obvious, immediate triggering action by the user. For example, accessing device location whenever it changes is a background use because it occurs without the user’s direct, immediate intervention. Whereas accessing device location after the user clicks a button is a foreground or interactive access. We describe the exact background usage scenarios we study in Section 3.2. From Nissenbaum’s theory of Privacy as Contextual Integrity [30] and prior work [3, 26, 29, 37, 42, 44, 45], we expect that users’ comfort should be significantly affected by the context of an access, including whether it is in the background.

3. METHODOLOGY

Our study focuses on background resource accesses, by which we mean accesses with no obvious, immediate triggering action by the user. For example, accessing device location whenever it changes is a background use because it occurs without the user’s direct, immediate intervention. Whereas accessing device location after the user clicks a button is a foreground or interactive access. We describe the exact background usage scenarios we study in Section 3.2. From Nissenbaum’s theory of Privacy as Contextual Integrity [30] and prior work [3, 26, 29, 37, 42, 44, 45], we expect that users’ comfort should be significantly affected by the context of an access, including whether it is in the background.

They found that the purpose shown had a significant effect on user comfort. We build on their study of user comfort by testing additional purposes, and we compare each purpose to the case where none is given to determine the effect of not informing the user. Also, we add additional variation in our conditions by testing both why and when the access occurs to study the relative strength of their effects and determine whether there is some interaction between these variables.

Other work has sought to study how user comfort is affected by the timing of resource uses (e.g., after a button is clicked, whenever the resource changes) [29, 12, 14, 45]. Wijesekera et al. study users in situ, measuring the effect of the app, whether the app is on screen, and the resource on whether users grant or deny resource access [44, 45]. Wijesekera et al. found that users were more likely to grant access when the request occurred whenever the app was being used. Micinski et al. study what resources users expect apps to access as they interact with the app (i.e., on startup, after a button is clicked, when no interaction is shown) [29]. They find that users expect resources to be accessed directly after a related interaction (i.e., camera is accessed after pressing a button labeled "Take a picture"), but do not always expect accesses that are not tied to an interaction. We expand on these findings by investigating comfort with the latter category of accesses.

Finally, there has been extensive work on Android permissions more broadly. User comfort has been studied in the context of app recommendation systems [27, 27, 28, 49], which use algorithms to help recommend apps to users based on their privacy preferences. Context has been used to drive static analyses and measure app behavior [9, 12, 19, 46, 48]. Lastly, Roesner et al. [35, 36] present Access Control Gadgets, which allows specific buttons in an app to authorize access to specific permissions.
(a) Survey procedure. Blue rectangles represent description portions of the survey. Orange, curved boxes represent question portions.

(b) Sample vignette for Datr app. In the app usage description, the orange boxes and arrows, and the gray circle, are not shown. They are added in in the resource access description step, along with the follow textual description: “While Jane was using Datr, the app behaved in the following way: Whenever Jane’s location changed, Datr learned about the change to her location and sent her updated location to datr.com. datr.com then used her updated location along with other updates it had collected on Jane previously to create a list of recommended singles based on places she has traveled in the past.”

Figure 1: User study survey procedure and sample vignette.

the data is accessed. For simplicity, we refer to when and why as the access context. As an example, consider an app that accesses device location every time the device moves and sends this data to a third party advertiser. The when is changing device location, and the why is advertising.

3.1 Study Overview

We performed a between-subjects, fractional-factorial vignette study [4]. Participants were recruited from Amazon’s Mechanical Turk crowd-sourcing service. All participants were at least 18 years old and located in the United States. After completing the vignette study, participants were paid $1.20. Participants took on average 4 minutes and 46 seconds to complete the survey. This study was approved by our organization’s ethics review board. Participants were asked for their opinions regarding a given app’s functionality and behavior, but we did not explicitly mention privacy or the possible sensitivity of specific resources.

Before beginning the main study, we piloted the survey with nine participants selected from a convenience sample, chosen in part for varying levels of technical knowledge. For each pilot, we asked participants to “think aloud” as they read the prompts and answered each question. We iteratively updated our survey following each pilot, eventually reaching the final instrument detailed below.

Figure 1 describes the survey procedure. First, the participant is shown a short description of the app. We used two mock apps in our study: Datr (Dating) and Ridr (Ride Sharing). Datr presents users with a list of singles they might like to meet, similar to popular dating apps like Tinder and Bumble. Ridr allows users to request rides to a selected destination, similar to popular ride sharing apps like Uber and Lyft. We do not attempt to fully study the effect of app type on user comfort, but instead simply include two apps from different categories to provide some insight into whether an effect may exist.

We begin each survey by describing how Jane, a fictional character, might use the app. We do so by showing a sequence of screenshots in which Jane first uses the app at home; then travels to a coffee shop and uses other apps; and then travels to the park and uses the app again. In this example, Jane presses “Request Ride” and is shown a list of recommended destinations.
After viewing the description of the app’s use, participants answer a simple question about the app’s functionality as an attention check (second item in Figure 1a). We include this check to reduce the risk of invalid responses.

Next, participants are informed of the app’s “behind-the-scenes” access context where they are shown the same series of app screens with additional indicators showing when and why the resource access occurred. Figure 1f shows that Datr collects Jane’s location whenever it changes (i.e., when she goes to the coffee shop and later to the park) and sends it to datr.com. The screenshots are also accompanied by a textual description, listed in the caption of Figure 1f explaining the scenario. The server then returns a list of recommended singles, to be displayed the next time she opens the app, based on Jane’s location. For each vignette, the set and order of app pages shown is the same, but we vary the when and the why (i.e., the orange boxes, gray circles, arrows, and text explanations).

For all scenarios where information is sent to a server, we show an arrow from the app to a circle labeled with a suggestive domain name. Kang et al. found that this was the most common convention used by non-technical users to draw information transmitted over a network [21].

After describing the app’s access context, we ask the participants a series of five-point Likert-scale questions. We begin by asking whether participants believe the access context is likely (“Very unlikely” to “Very likely”) to appear in popular apps and whether they agree (“Disagree” to “Agree”) the behavior makes the app more useful. We ask these questions because we expect that participants’ comfort with an access context is likely affected by their prior exposure to similar scenarios and perceived usefulness of the behavior to the user [31, pg. 133-140].

Next, we directly assess the participant’s level of comfort by asking whether they would feel “Very uncomfortable” to “Very comfortable” using an app with the described access context. Additionally, we ask whether they would be “Very unlikely” to “Very likely” to recommend an app with the described access context to a friend who is looking for an app with the given functionality. We add this question to indirectly measure participant comfort.

Some participants were assigned to a condition in which the why is not given. In these conditions, we ask participants to provide a short, open response description of why they think the access occurred.

Finally, we conclude with a set of questions about the participants’ Internet skill level and demographics. We measure Internet skill using the seven-question scale proposed by Hargittai and Hsieh [17]. Each question on the scale asks participants to rate their familiarity with a different Internet-related term, from “No understanding” to “Full understanding.”

### 3.2 Conditions and Hypotheses

Within this study design, we developed a set of conditions varying over four variables: the app, the resource being accessed, when the resource was accessed, and why the app accessed the resource. Table 1 lists the levels for each variable.

<table>

Table 1: Possible values for each variable in tested conditions.

#### Reasons for resource access.

We used five variations for why the app collected the sensitive resource. In the personalize (Personalize) case, users were told the app collected data to provide personalized features. Additionally, this case stated that no data was sent off device (i.e., to the app’s server or any third party). Server (Server) is similar, but users were told data was first sent to the app’s own server to support personalization. For example, the Dating app sends the user’s information to the server to retrieve a list of personalized dating matches. Debugging/Analytics (Analytics) stated that the app shared data with a third-party for debugging crashes and collecting analytics to improve the app. For Advertising (Ads), participants were told the app sent their collected data to a third-party advertiser to improve ad targeting. We also include a Not Given (NA) case, in which the participant was not given a reason for data collection.

These scenarios map to our first two hypotheses, as follows.

**H1. The provided reason for resource access affects participants’ comfort levels.**

Within this broad hypothesis, we test three sub-hypotheses concerning specific categories of possible reasons for resource access.

**H1a. Users are more comfortable if their information is kept on their device.**

**H1b. Users are more comfortable if their information is not shared with a third party.**

**H1c. Users are more comfortable if their information is only shared with a third party to improve general app functionality, as opposed to advertising.**

Notice that each of these hypotheses represents an increasing degree of willingness to share information.
We test \(H1a-c\) by searching for divergence among our why levels. If \(H1a\) is true, then we would expect to see a gap in comfort between \textit{Personalize} and \textit{Server}. Similarly, \(H1b\) indicates a divide between first party (i.e., \textit{Personalize} and \textit{Pre}) and third party (i.e., \textit{Analytics} and \textit{Ads}) sharing. Finally, \(H1c\) is true if there is a significant difference in comfort between \textit{Ads} and the other levels.

\textbf{H2. Users are more comfortable if given a reason for background use.}

While \(H1\) investigates how different reasons for resource access compare in terms of user comfort, \(H2\) asks how these different explanations compare to the lack of an explanation. Prior work in psychology has shown that people are generally more accommodating when given a reason for a request, no matter how vague \cite{24}. \(H2\) tests whether this is the case for background resource accesses. If \(H2\) does not hold, then perhaps in some cases the reason for access can be omitted from access notifications or requests, reducing cognitive burden on users without causing undue discomfort.

\textbf{Triggers for resource access.} We considered five variations in when the app requests resources. UI-Interactive (Int) describes the case where an app accesses a resource after a directly related UI event (e.g., a button click). We include this case, which is not a background access, as a control that mimics the interactive resource use patterns described by Micinski et al., which led users to expect resource accesses \cite{29}.

Prefetch (Pre) is similar to \textit{Int}, as the UI indicates that the resource is accessed. However, the actual resource access occurs prior to the UI event (on startup of the application), so that the accessed data is ready to present when the user performs the UI action. In the \textit{Pre} case, there is no visual indication of access when the data is collected, but the user is eventually made aware. UI-Background (UI-Bg) presents the same behavior as \textit{Int}—access after a UI event—except the UI event is unrelated to the resource access. Finally, On Change (Change) describes an app that accesses a sensitive resource directly after that resource has been modified (e.g., the user changes location or adds/deletes a contact). Note that a \textit{Change} access—unlike UI-Bg and \textit{Int}—can occur whether the app is or is not currently in use.

These variations map to our final hypothesis:

\textbf{H3. Users have different comfort levels when resource accesses are triggered by different events.}

Prior work has considered two dichotomous categorizations of access triggers: On-screen vs. off-screen \cite{44} and interactive vs. non-interactive \cite{29}. We use the following sub-hypotheses to understand user comfort across and between these categorizations, with more fine-grained distinctions.

\textit{H3a. Users are more comfortable with sensitive resource accesses when they are interactive.}

\textit{H3b. Users are more comfortable with sensitive resource accesses when there is an explicit foreground visual indicator of use, even if the use occurs before the indicator.}

\textit{H3c. In the absence of an explicit foreground visual indication of use, users are more comfortable when the app is on-screen than when it is off-screen.}

To examine \textit{H3a}, we compare \textit{Int} to all the other levels. To examine \textit{H3b}, we compare \textit{Pre} to the other background levels. Finally, to examine \textit{H3c} we compare UI-Bg to \textit{Change}.

\textbf{Apps and resources.} As stated previously, we use two mock apps, \textit{Datr} (Dating) and \textit{Ridr} (Ride Sharing). We selected three resources which were found by Micinski et al. to be used with both foreground and background interaction patterns: Location (Loc), Contacts (Con), and Text Messages (SMS) \cite{29}. We test multiple resources because prior work has shown that grant/deny rates varied between permission types \cite{7}.

\textbf{Final condition set.} Because the full-factorial combination of all levels of each variable creates too many conditions to be feasibly tested, we discarded combinations that were redundant, logically inappropriate, or less relevant to our hypotheses. After this reduction, we were left with 52 final conditions.

First, we removed any condition that includes \textit{Int} or \textit{Pre} together with \textit{NA}. Since a reason for the resource access is directly presented to the user through the UI (i.e., the button text clearly states that the resource is accessed to provide personalization of a feature), \textit{Int-NA} and \textit{Pre-NA} are redundant with \textit{Int-Personalize} and \textit{Pre-Personalize}, respectively. Therefore, \textit{NA} is only included with UI-Bg and Change. This is shown in Table 1 by the orange highlight of \textit{NA} and indicated by the superscript 4.

As we do not intend to completely investigate the effect of app type and resource, we restrict the \textit{Ride Sharing} and SMS conditions to only include levels where we expect to observe the largest variation in comfort. Specifically, with \textit{Ride Sharing}, we only test the resource SMS; the why levels \textit{Analytics} and \textit{NA}; and the when levels \textit{Int} and \textit{Pre}. In Table 1 all the highlighted levels are never considered with \textit{Ride Sharing} as indicated by the superscript 5.

For SMS, we do not test the why levels \textit{Analytics} and \textit{NA} or the when levels \textit{Int} and \textit{Pre}. The levels that are never associated with SMS are highlighted in blue, orange, and yellow and indicated by the superscript 6.

Finally, due to the similarity in presentation between \textit{Pre} and \textit{Int}, we limit the levels included with \textit{Int} to only those where we expect to observe the largest variation in comfort. Therefore, we do not consider \textit{Analytics} with \textit{Int}. In Table 1 we highlight in blue—and indicate with the superscript 7—the levels that are never included with \textit{Int} due to this rule.

\subsection*{3.3 Statistical Analysis}

For all Likert-scale questions, we use a logistic regression (appropriate for ordinal data) to estimate the effect of the assigned condition on the participant’s comfort, likelihood to recommend the app to others, perceived usefulness of the app behavior, and perceived likelihood that this behavior occurs in popular apps.

For each question, our initial regression model included all the factors and interactions given in Table 2. We applied the standard technique of centering the numerical factor (Inter-
network skill) around its mean before analysis to promote interpretability [10]. To determine the optimal model, we calculated the Bayesian Information Criterion (BIC)—a standard metric for model fit [33]—on all possible combinations of the given factors. To avoid overfitting, we selected the model with the minimum BIC. This process was completed for each regression separately.

Additionally, to understand what participants believed about the reason for data collection when none was explicitly given (i.e., the NA level of the when factor), we performed an open coding of participants’ free responses. Two researchers individually reviewed each response in sets of 30 and iteratively developed the codebook. The coders reached a Krippendorff’s α of 0.831 after three rounds of pair coding (i.e., 90 responses), which is within the recommended bounds for coding agreement [18]. The remaining responses were divided evenly and each coded by a single researcher.

3.4 Limitations
Our reliance on mock apps for our controlled experiment limits the ecological validity of our study. We chose this setting because it allows us to reason about the statistical effect of specific factors on participant comfort. Additionally, using mock apps allows us to disregard possible confounding factors such as participants’ prior experience with an app or its developer’s reputation. However, in this controlled setting, users may be less concerned about their privacy than if their real data were at risk. They may also overstate their discomfort because they are not actually using the app and therefore not placing emphasis on the functionality benefits gained by allowing access to their personal data [39]. To partially account for this, we ask about comfort both directly and indirectly (i.e., would they recommend the app to a friend) and include a description of the app functionality that is dependent on the given behavior scenario. Additionally, we only rely on comparative, rather than absolute, results when analyzing responses.

Limiting our study to two types of apps and restricting the resources and access contexts tested is likely to cause us to miss potential factors, especially interactions between factors that affect user comfort. For example, users are likely to expect different types of apps to use resources differently depending on the app’s functionality, and these differences in expectations are likely to affect comfort. In attempt to reduce this problem, we selected conditions based on a review of prior work and manual app reverse engineering.

For each finding from our open-response questions, we report the percentage of participants that expressed a concept. However, a participant not mentioning a specific idea does not necessarily indicate disagreement. Instead, they may have simply failed to state it or they may not have thought it the most likely possibility. Therefore, our results from open-response questions should be interpreted as measuring what was at the front of participants’ thoughts as they responded to the questions.

As is common for any online studies and self-reported data, it is possible that some participants do not approach the survey seriously, and some may try to make multiple attempts at the survey. We limit repeat attempts by collecting participants’ MTurk ID and compare these to future attempts to restrict access. Though MTurk has been found to produce high-quality data generally [11, 23, 43], the U.S. MTurker population, from which we drew participants, is slightly younger and more male, tech-savvy, and privacy-sensitive than the general population [20]. This restricted population may affect the generalizability of our results.

However, we consider comparisons between conditions to be valid because each of these limitations apply similarly across all conditions.

4. PARTICIPANT DEMOGRAPHICS
A total of 2,797 participants attempted our survey. Of these, 2,328 (83.2%) finished. From these, we removed several participants who had previously taken the survey. We also removed 121 participants (5.2%) who failed an attention check. We ultimately had 2,198 total responses, with between 40 and 45 responses per condition.

Demographics for our participants are summarized in Table 3. Participants were more male and more white than the U.S. population, as is expected from MTurk. Additionally, our participants’ average Internet skill of 32.2 was slightly higher than the mean score of 30.5 recorded by Hargittai and Hsieh on a more general population several years ago [17]. The vast majority of participants use smartphones regularly. The proportion of accepted participants who own a smartphone (99%) is well above the reported U.S. average of 79% reported by Pew [41]. The majority of participants (97%) also considered themselves to have at least “Average” smartphone expertise on a five-point scale from “Far below average” to “Far above average.”

5. RESULTS

In our online vignette study, we found that both why and when resource accesses occurred had a significant effect on user comfort. Additionally, we found that there are several meaningful classes of accesses for each part of the access context.

With respect to why the access occurred, we observed that users were more comfortable when data was shared with the app developer (Personalize and Server) than a third-party (Analytics and Ads). Further, within third-party sharing, users are more comfortable when data is shared for app analytics (to improve the functionality of the application) as opposed to sharing data for advertising. Additionally, if no reason for access was provided, we found that users were less comfortable than they would be if told the data never left their device (Personalize), but slightly more comfortable than having their data shared with advertisers (Ads).

For when, as expected, users are the most comfortable when accesses occur interactively, directly after a UI event (Int). Non-interactive (background) accesses can further be divided into two classes: participants were more comfortable if the access occurred when the app was on-screen (Pre and UI-Bg) compared to off-screen (Change). Detailed descriptions of these results are given below.

Interpreting regression results. The majority of our key findings are drawn from our regression analysis over the users’ comfort (Table 4a). We also discuss regression analyses for willingness to recommend an app with a given behavior (Table 4b) and belief that the app’s behavior is useful (Table 5). Overall, these regressions produced very similar significance results. Our discussion will therefore focus primarily on comfort results.

All three regression tables show (as groups of rows) the variables included in the final selected model. For each categorical variable, we present the base case first. We selected base cases that we expected to produce the highest levels of comfort. For why, we selected Personalize because it involves the least data sharing. For when, we selected Int because it is the most interactive, which has been shown to correlate with user expectation of resource access. For resource, we selected Loc based on prior work that suggests users are more comfortable with apps accessing location than other sensitive resources.

In the odds ratio (OR) column, we show the variable’s observed effect. For categorical variables, the OR is the odds of comfort increasing one unit on our Likert scale when changing from the base case to the given parameter level. For the numeric variable (Internet skill), the OR represents the odds of comfort increasing one unit on our Likert scale, per one-point increase in Internet skill. The OR for the base case (categorical) and the average Internet skill (numeric) is definitively 1.0. For each value, we also give the 95% confidence interval for the odds ratio (CI) and the associated p-value.

As an example, the odds ratio for Pre in Table 4a indicates that a user who is assigned to Pre rather than Int—assuming all other variables are the same—would lead to a 0.64x likelihood of increasing one unit in comfort. Because this effect is less than one, participants are less likely to report higher comfort levels for Pre than Int. In short, users are less comfortable with Pre. Furthermore, Pre’s CI indicates that the “true” odds ratio is between 0.48 and 0.87 with 95% confidence. The p-value of 0.004 is less than our significance threshold of 0.05, so we consider this difference between Int and Pre to be significant.

5.1 H1 and H2: Reasons for resource access

For H1 and H2, we primarily focus on the why variable, shown in the first section of Tables 4a and 4b.

Data leaving the device (H1a). We first consider whether resource accesses in which data remains on the device (Personalize) are more comfortable for users than those in which data is transferred to the app company’s server (Server). The first two rows of each Tables 4a and 4b indicate that Personalize and Server are not significantly different from each other. This is illustrated in Figure 2, which shows participants’ Likert responses to the main comfort question, grouped according to the why scenario they were shown. In the Personalize condition, 44% selected comfortable or very comfortable, compared to 42% in the Server condition.

Table 5 shows the results of our logistic regression for whether the app’s behavior is useful. This provides additional insight into participant preferences, as users may be more willing to tolerate uncomfortable behavior if it is useful. As shown in this table, the Personalize and Server conditions also do not differ significantly from each other in perceived usefulness.

We therefore conclude that H1a does not hold. This corroborates, at a larger scale, the findings of Shklovski et al., who showed that users were comfortable sharing information off device if it was only used by the app’s developer.

First vs. third parties (H1b). We next consider whether participants responded to first-party accesses (Personalize and Server) differently than third-party accesses (Analytics and Ads). Figure 2 shows that participants were overall less comfortable with the third party accesses. Across our two first-party conditions, 43% of participants responded comfortable or very comfortable, compared to only 25% across our two third-party conditions.
As shown in Table 4, differences between first- and third-party explanations are statistically significant. The Analytics and Ads conditions are associated with significantly less comfort than the base Personalize case. Further, the confidence intervals for Analytics and Ads do not overlap with the base condition, indicating that the two third-party conditions are each significantly different from the first-party Server condition as well. The same significance relation holds for app recommendations, as shown in Table 4b. In terms of effect size, the relative odds ratios among the first- and third-party conditions indicate that participants in third-party conditions were between one-third and two-thirds as likely to report a higher level of comfort than were the first-party participants. For example, participants were 0.6 times as likely to report a higher level of comfort for Analytics than for Server (0.49/0.80), and 0.46 times as likely for Ads than Server (0.34/0.80). The effect sizes for willingness to recommend were similar: 0.6 times (0.51/0.91) and 0.3 times (0.27/0.91), respectively.

A similar analysis of Table 5 shows that participants found the behavior of apps in the third-party conditions (Analytics, Ads) to be significantly less likely to be seen as useful than the behavior of apps in the first-party conditions (Personalize, Server).

Overall, we conclude that H1b holds, and that the difference between first- and third-party accesses is meaningful.

**Analytics vs. advertising (H1c).** We find partial evidence to support H1c, which concerns the difference between our two third-party conditions. With respect to our main comfort question (Table 4a), the confidence intervals between Analytics and Ads overlap, indicating no significant difference between the two. However, comparing confidence intervals in Table 4b does show that participants were significantly more likely to recommend the app in the Analytics condition than in the Ads condition. Ads participants were only 53% (0.27/0.51) as likely to report a higher level of recommendation. Perhaps unsurprisingly, a parallel reading of Table 5 indicates that participants also found Analytics more useful than Ads.

---

Figure 2: Likert-scale comfort organized by reason for resource access.
Perception when no why is provided (H2). To test H2, we compare the NA condition, in which no reason is provided, to all the other why conditions. Overall, we find that H2 holds partially; a lack of explanation is more comfortable than some explanations, but less comfortable than others.

Inspection of Figure 2 suggests that the NA condition falls in the middle of the pack in terms of expressed comfort; 33% of participants in this condition reported being comfortable or very comfortable with this behavior.

Referring again to the top section of Table 4a, we see that this “middle” impression is reflected in our statistical analysis. The NA condition is worse than the most comfortable case, with a point estimate of 0.58× the likelihood of higher comfort compared to the baseline Personalize condition. On the other hand, comparison of odds ratios suggests that the NA condition is slightly (but significantly) better than the worst case (Ads). Comparing odds ratios with the other why levels, we see that NA is not significantly different from Server or Analytics. The same trend—worse than Personalize but better than Ads—holds as well for responses to the recommendation question (Table 4b). With respect to the usefulness of the app’s behavior, Table 5 indicates that NA scenarios were seen as less useful than Personalize and Server, but not different than Analytics or Ads.

We asked participants in the NA condition to provide an open-ended explanation for the resource accesses they were shown. Figure 3 shows how many participants (grouped according to the type of resource access they were shown) provided each of the most common reasons, according to our manual coding. (Note that an individual participant could provide more than one reason, so totals are greater than 100%.)

By far the most common response (76% of all NA participants) was that resource accesses were used for personalization. For example, one participant said Jane’s location was accessed to “find singles that are nearby.” The second-most common response was advertising (24% of all NA participants).

Our regression results suggest that a lack of explanation (NA) is less comfortable and useful than Personalize, even though most participants’ assumed the resource access was actually for personalization. Because participants generally did not distinguish between on- and off-device personalization, these personalization responses can be considered roughly equivalent to either our Personalize or Server conditions. One potential explanation is that the uncertainty associated with a lack of explanation creates some discomfort, even when participants assume that the underlying explanation is acceptable.

Summary of why results. Overall, our results for H1 and H2 suggest that both who sensitive data is shared with and why matter: accesses used only by the app company for personalization are most comfortable, followed by third-party accesses associated with analytics, with third-party accesses for advertising least comfortable.

5.2 H3: Triggers for Resource Access

We next examine the effect of our when variable on users’ responses, shown in the second group of results in Tables 4a, 4b, and 5, labeled when.

Interactive vs. non-interactive accesses (H3a). We first compare our three non-interactive triggers to the Int control condition, to validate that interactive accesses are more comfortable. We find that, as expected, H3a does hold. As shown in Tables 4a, 4b, and 5, we find that Int is associated with statistically significantly higher levels of comfort, willingness to recommend, and usefulness compared to every other when condition. Point estimates range from 1.4× (1/0.72, UI-Bg) to 2.9× (1/0.34, Change) more likely to report a higher comfort level.

Figure 4, which shows participants’ Likert responses to the comfort question organized by when condition, illustrates this comfort gap between Int and the other when conditions.

Importance of visual indicator (H3b). We next consider whether an explicit foreground indication of use can increase user comfort, even if the indication happens after the access. In particular, we compare the Pre condition to the other background when conditions.
Comparison of odds ratios in Table 4a suggest that H3b holds partially: Pre is associated with significantly higher comfort levels than Change (1.9 ×, 0.64/0.34), but is not significantly different from UI-Bg. The same pattern holds for willingness to recommend and for usefulness, shown in Tables 4b and 5.

**On-screen vs. off-screen (H3c).** Finally, we compare the two when conditions with visual indicators: UI-Bg, which only includes background accesses while the app is on-screen, and Change, which includes accesses while the app is off-screen. We find that, as might be expected, off-screen accesses are significantly less comfortable, meaning H3c holds.

This finding can be observed visually in Figure 4, which shows that only 24% of participants were comfortable or very comfortable with the Change scenario. As shown by comparing odds ratios in Table 4a, this difference is significant: the point estimate suggests that Change is only 0.47× as likely to be associated with higher comfort as UI-Bg (0.34/0.72). Tables 4b and 5 exhibit the same significance relation for willingness to recommend and usefulness, respectively.

**Summary of when results.** Taken together, our results for H3a–H3c suggest three distinct classes of access triggers: interactive accesses, non-interactive (background) accesses that occur when the app is on screen, and background accesses that occur when the app is off screen.

### 5.3 Other Findings

As described in Section 5.3, our regression analysis included several other covariates beyond why and when. The final two groups of results shown in Table 4a indicate that the resource shown (Loc, Con, or SMS) and the participants’ Internet skill both had significant effects on comfort. In particular, participants reported highest levels of comfort with the baseline Loc resource. Access to Con was also significantly (2.8 ×, 0.33/0.12) more likely to be comfortable than access to SMS. This aligns with prior work from Felt et al. [14].

Additionally, we observed that users who scored higher on Hargittai and Hsieh’s Internet skill scale [17] were significantly likely to be less comfortable (OR 0.95, p < 0.001). This means that a participant with the maximum possible score of 35 would be about 0.87× (0.95⁻²⁸⁻⁸) as likely to express increased comfort as a participant with the mean score of 32.2. This result is analogous to Liccardi et al.’s finding that users with less understanding of how apps operate were more likely to download apps requiring additional significant permissions [23].

Resource type and Internet skill exhibited similar significance relations in willingness to recommend and usefulness (Tables 4b and 5, last two sections), with one exception: accesses to SMS were not viewed as significantly less useful than accesses to Con.

Notably, none of the interactions we considered (Table 2) appeared in the final minimum-BIC model for any of our outcome variables. This suggests that these variables—most importantly, the when and why context factors—can be considered independent from each other.

Similarly, app type was not included in any of the final models, meaning we did not observe a significant difference between participants’ responses to the Datr and Ridr apps. However, because we only tested two apps, we cannot conclude that the app has no effect on user comfort.

Finally, we observed that a large percentage of participants stated they were uncomfortable or very uncomfortable in all the tested why and when conditions. In fact, Int was the only condition where the majority of participants expressed comfort. In practice, of course, users do use apps with these sorts of background uses. Thus, we see that, as might be expected, participants tend to over-report the magnitude of their privacy concerns.

### 6. DESIGN RECOMMENDATIONS

Based on the results of our study, we make several recommendations for designers of mobile-privacy systems:

**Apps using the same resource for multiple reasons should make this explicit.** Several systems have been proposed to help users make informed decisions according to their privacy preferences, with context in mind [28, 29]. In each, the authors group various access contexts together. We found that such groupings may be insufficiently nuanced. For example, Wijesekera et al. learn user preferences based on whether the app is on- or off-screen at the time of access [45]. This grouping conflates Int, Pre, and UI-Bg, which all occur when the app is on-screen, but were associated with significantly different user comfort levels in our study. Miciński et al. make an opposite split, recommending that interactive accesses be treated differently from those that are not associated with user interaction [29].

Again, this oversimplifies user comfort with non-interactive accesses: our results show significant differences between Pre and UI-Bg, in one class, and Change in another.

As a positive example, the privacy assistant developed by Liu et al. divides reasons for resource access into first-party, analytics, and advertisement bins [28]. This grouping accounts for the differences in user comfort we observe in the why context. Future such systems should attempt to accurately capture nuanced resource-access classes across both when and why.

**Users Incorrectly Rationalize Uses Presented Without Reason.** When no reason for an access is given, we found that users are too generous in their assumptions about access context. For example, in absence of explanation, users will tend towards assuming data is being used for personalization (although with slightly lower comfort, perhaps due to uncertainty). If an access is actually used for advertising (or worse, for both advertising and personalization), users might authorize more access than they are actually comfortable with. On the other hand, if data is actually used only for personalization or remains on the device, providing this information could allow the user to feel more comfortable allowing a request than they otherwise would.

Both in Android and iOS, by default whenever an app requests permission to access a sensitive resource, no reason is given for that access. Both systems allow developers to provide a reason, but in practice very few developers take advantage of this feature [19]. Users should be skeptical of any access presented without an explanation, since developers are disincentivized to explain accesses that are used for advertising. Perhaps the Android API could require an
explanation from a fixed set of options, or even default to a “may be used for advertising” explanation if the developer fails to provide a reason. Legitimate developers could presumably be incentivized to provide accurate information to avoid charges of fraud or deceptive practices (analogous to privacy policies).

Users Care Where Their Data Goes. Last, we found that access control alone does not suffice to ensure user comfort. In terms of our study, traditional access control corresponds to the *when* but not the *why*. We also found that where data ultimately ends up has a statistically significant effect on user comfort. For example, users were significantly more comfortable with data being accessed as long as it remained on the device rather than being exfiltrated for advertising. Significant research effort has been devoted to tracking data as it flows through apps [3,13]; our results underscore the importance of using such systems, alongside traditional access control, so that the *why* can complement the *when* in users’ contextual decision making.

7. CONCLUSION
In this work, we used a 52-condition, 2,198-participant vignette study to examine how the context of a sensitive resource access in Android—defined as both *when* and *why* the access occurs—affects user comfort with that access. In particular, we examined whether users think similarly about different kinds of background resource accesses, or whether there are important distinctions that determine users’ comfort with those accesses.

We found that both *when* and *why* a sensitive resource access occurs have a statistically significant effect on user comfort, and that there are meaningful differences between classes of accesses within both access context variables. While users are most comfortable with interactive accesses, they also make distinction between non-interactive accesses occurring when an app is on--screen as compared to off-screen. Similarly, users are more comfortable with first-party than third-party accesses, but also make a distinction between third-party accesses for analytics as compared to advertising. We recommend that designers of mobile-security systems not only consider both *when* and *why* a resource access is requested, but also respect nuanced distinctions that influence user comfort.

### APPENDIX

#### A. SURVEY QUESTIONNAIRE

App usage description and attention check.

While at home, Jane decides to use Datr to look for other singles. She opens the app and presses the button “Find Singles”. The app then shows her a screen with a list of recommended singles.

Jane closes the app and travels to a nearby coffee shop where she meets her friend, Sarah. As they get ready to leave, Jane realizes she does not have Sarah’s contact information. Jane adds Sarah to her phone’s contacts and Sarah sends Jane a text message to remind her that they should meet again some time.
After leaving the coffee shop, Jane heads to the park. She decides to check Datr again and is presented with a new list of singles.

1. Which of the below options best describes the set of steps Jane would have to take to indicate that she is interested in Person 9?
   (a) Press the heart-shaped icon next to Person 9
   (b) Press the X icon next to Person 12
   (c) Press the reload symbol

Resource access description and study questions.

While Jane was using Datr, the app behaved in the following way:

Whenever Jane’s location changed, Datr learned about the change to her location and sent her updated location to datr.com. datr.com then used her updated location along with other updates it had collected on Jane previously to create a list of recommended singles based on places she has traveled in the past.

For the remaining questions, we’re going to ask you about an app like Datr that collects your location whenever your location changes and sends it to its server to provide personalized features and does not send your location to other parties.

1. Do you think popular dating apps collect your location whenever your location changes and send it to its server to provide personalized features and do not send your location to other parties?
   (a) Very likely
   (b) Likely
   (c) Neither likely nor unlikely
   (d) Unlikely
   (e) Very unlikely

2. Please indicate your level of agreement with the following statement: A dating app like Datr is more useful when it collects your location whenever your location changes and sends it to its server to provide personalized features and does not send your location to other parties?
   (a) Agree
   (b) Somewhat agree
   (c) Neither agree nor disagree
   (d) Somewhat disagree
   (e) Disagree

3. Suppose you were interested in using a dating app like Datr. How would you feel about using a dating app that collects your location whenever your location changes and sends it to its server to provide personalized features and does not send your location to other parties?
   (a) Very comfortable
   (b) comfortable
   (c) Neither comfortable nor uncomfortable
   (d) Uncomfortable
   (e) Very uncomfortable

4. Suppose you know someone who wants to use a dating app like Datr. If you had to recommend an app for them to use, would you recommend an app that collects your location whenever your location changes and sends it to its server to provide personalized features and does not send your location to other parties?
   (a) Very likely
   (b) Likely
   (c) Neither likely nor unlikely
   (d) Unlikely
   (e) Very unlikely

Note: For the none case we also included the following free response question

5. Please provide a short description of why you think Datr is interested in knowing Jane’s location.

Internet skill questionnaire.

1. How familiar are you with the following computer and Internet-related items? (Items: Reload, Bookmark, Advanced Search, Favorites, Tagging, Preference Settings, PDF) (Choices: No Understanding, Little Understanding, Good Understanding, Full Understanding)

Demographics.

1. What is the highest level of school you have completed or the highest degree you have received? (Choices: Less than high school degree, High school graduate (high school diploma or equivalent including GED), Some college but no degree, Associate degree (2-year), Bachelor’s degree (4-year), Master’s degree, Doctoral degree, Prefer not to answer)

2. Please specify the gender with which you most closely identify. (Choices: Male, Female, Other, Prefer not to answer)

3. Please specify your ethnicity. (Choices (may choose multiple): Hispanic or Latino, Black or African American, White, American Indian or Alaska Native, (Asian, Native Hawaiian, or Pacific Islander), Other, Prefer not to answer)

4. Please specify your age.

5. Please select the response option that best describes your household income in 2017, before taxes. (Choices: Less than $5,000, $5,000 - $14,999, $15,000 - $29,999, $30,000 - $49,999, $50,000 - $74,999, $75,000 - $99,999, $100,000 - $149,999, $150,000 - $199,999, $200,000 or more, Prefer not to answer)
6. Please select the response option that best describes your current employment status. (Choices: Working for payment, Unemployed, Looking after home/family, Student, Retired, Unable to work due to permanent sickness or disability, Other(specify), Prefer not to answer)

7. How many hours a day do you use your smartphone? (Choices: 0-3, 3-6, 6-9, 9+, Unsure, I do not own a smartphone)

8. Rate your expertise using a smartphone. (Choices: Far above average, Somewhat above average, Average, Somewhat below average, Far below average)
